

01

With JavaScript connectors you can write custom authentication endpoints. This allows you to bypass the SQL datastores and control authentication through your own applications.

```
1  component rest="true" restpath="authentication" Name="OAuth"{
2
3      //GET Request to return customers
4      function doAuthentication () access="remote" returnType="struct" produces="application/json" httpmethod="POST" {
5          var response =
6              {
7                  status=401,
8                  content="Failed Auth",
9                  headers={
10                      location=""
11                  }
12              }
13          restSetResponse(response);
14          return response;
15      }
16  }
```
